

REMOTE CONTROL SYSTEM FOR AN ACCESS DOOR
HAVING REMOTE TRANSMITTER VERIFICATION

Abstract of the Disclosure

A remote control system for moving an access door includes an indicator, at least one uniquely coded remote transmitter, and a controller that is switchable to a learning mode for learning a unique code of a remote transmitter to define a learned remote transmitter. The controller is switchable to a door moving mode based upon receiving a signal from the learned remote transmitter. The controller cooperates with the indicator for indicating whether a new uniquely coded remote transmitter has been learned based upon the controller being switched to the door moving mode to thereby alert a user of a potentially unauthorized learned remote transmitter. Alternately, a remote switch may be used to activate the indicator.
